ABSTRACT

This Thesis reviews the increasing need for security in a personal computer (PC) environment and proposes a new approach for securing PC applications at the application layer. The Relay Race Approach extends two standard approaches: data encryption and password access control at the main program level, to the subprogram level by the use of a special parameter, the "Baton". The applicability of this approach is demonstrated in an original Basic application and an existing Dbase IV application, representing both third generation language (3GL) and fourth generation language (4GL) environments. The Approach can add to overall network security in the PC LAN environment as well. The Approach is successful and proposed enhancements can strengthen the Approach.

I. INTRODUCTION

The proliferation of information systems in virtually all areas of business and government has increased the importance of computer security issues. As more people become computer literate, the risks of ill-intentioned individuals obtaining unauthorized access or violating the integrity and validity of data grow. Potential solutions to computer security risks are varied and numerous because different types of computer hardware, operating systems, and application software have different security strengths and weaknesses.

Different environments and applications require varying levels of security and security measures. Some environments need to target their security measures toward threats of accidental data corruption while others are primarily concerned with unauthorized access to sensitive information. Another computer security issue is system protection from viruses, worms, trojan horses, etc.

Widespread use of personal computers and growth of end user computing have introduced myriad security concerns. Almost every personal computer user is likely to view virus protection, data backup, floppy disk control, and data encryption as primary computer security issues (Murray 1989, Stephenson 1989, Brown 1989). However, many personal

computer security concerns for the most part remain largely unaddressed at this time (Pfleeger, 1989). Moreover, the growing population of knowledgeable personal computer users increases the numerical chances of security breaches involving personal computers.

This research explores the unique security issues involving personal computers and proposes a new approach for securing personal computer applications and data.

II. SECURITY IN PERSONAL COMPUTERS

The use of personal computers, including microcomputers, office automation workstations and intelligent workstations, has spread substantially in recent years. Since the introduction of these systems, in the late 1970s, they have undergone far reaching changes and improvements which have brought them almost to the level of performance of large computers (Giladi and Zviran, 1989). Analysis of the development and characteristics of personal computers and large systems shows that the processing speed of present personal computers is equal or even superior to that of the main large systems that were in use during the late 1970s (e.g., IBM 370 series).

The basic security problems for personal computers are the same as those for every other computing environment: applications require secrecy, integrity and availability applied to programs and data. However, security problems of personal computers are more serious than those of mainframes or mini computers due to the lack of security tools and mechanisms. Many of the hardware and software facilities important in assuring security are inappropriate and unavailable in the personal computer environment.

The security problem of personal computers is becoming even more meaningful as these machines are being integrated

into computer networks. While many personal computers are being used in a stand-alone mode, others are being connected to networks as front-end terminals and processors, becoming a weak link in the network security chain. This problem becomes more crucial in the open system interconnection (OSI) environment. As the goal of an OSI environment is approached it becomes easier and more economical to connect computers and share resources. Logically, more PCs will be integrated into network systems. As a result, national organizations as well as users are becoming concerned with the vulnerability of personal computers (NCSC, 1985; NTISSC, 1987; Post and Kievit, 1991).

As the name implies, personal computers were initially envisioned as being used by one person. Simple physical security measures would supply the necessary measure of security. This single user view is evident in the design of the popular personal computer operating system, MS-DOS. In most organizations today however, PCs are not personally allocated (Gogan, 1991). In view of this, more security is sometimes required. There is a definite lack of tools to provide security for personal computers.

As the popularity and power of personal computers grows, more people want and obtained access to them. Personal computers distribute computing power to virtually all physical locations within an organization, unlike large

machines. For the first time the computing power is not under the control of computer professionals. Persons responsible for mainframe or mini-computer security have limited control over how personal computers were being used within organizations. Generally, personal computer users lack the sensitivity toward computer security issues exhibited by mainframe and mini computer operators. The personal and organizational computer security mechanisms evident in large systems are not automatically in place for personal computers.

A. HARDWARE

The first IBM personal computer was built around the 8088 processor. This processor had no protection scheme. All memory locations were open and unguarded. There were no privileged instructions available only to the operating system or trusted kernel. The newer 80286 and 80386 CPUs have stronger protection capabilities but the MS-DOS operating system is not capable of exploiting them (Post, 1991; Pfleeger, 1989).

Common hardware add-on security measures include physical security measures, security modules, and locks and keys. Each provides various degrees of security against certain types of threats while exhibiting weaknesses against others.

Locking doors to rooms containing computers is effective but in most cases not feasible. Too often it is necessary to allow open access to a room containing the computer. Disconnecting and locking the computer's keyboard in a desk drawer or cabinet provides good security without limiting access to an office space. Unfortunately, physical security measures limit access to all of the computer's programs, not just the sensitive ones. This weakness can lead to under-use of computer assets.

Security modules are expansion boards which plug into industry standard slots on personal computer motherboards to provide security. They usually perform in concert with software utilities. Security modules usually prevent booting from other than the fixed hard disk drive. This ensures that access control software stored on the fixed disk is run upon boot-up. Because the modules must plug into standard slots for compatibility reasons it would be easy for an intruder to locate and remove them. Many casual personal computer users possess sufficient knowledge to quickly open a computer's case, identify specific expansion boards and remove the security module (Stephenson, 1989; Zarger, 1988).

Key type locks coupled to power switches are often used in personal computers as security measures. These locks are an "all or nothing" device. Those who have a key have

access to all programs and data and those who do not have a key have access to nothing. They cannot provide universal access to public applications and provide security for private programs and data. Additionally, locking power switches can be defeated quite easily if the computer is housed in a standard case. Once the standard "easy access" case is opened, it is a simple matter to "hot wire" the switch to defeat the lock.

Hardware security solutions are enhanced when cases and fasteners are used which are non-standard and require special tools or keys for access or removal. Additionally, epoxy coatings are useful in protecting hardware items from tampering measures such as hot wiring switches. As with most security issues, using optimum combinations of security measures greatly enhances personal computer security effectiveness.

B. SOFTWARE

Any computer system has, usually, two different types of software: an operating system and application programs. The operating system consists of the system programs, command interpreter, and utilities. The operating system is the focal point for exploring security issues. Application programs are those which accomplish processing desired by

the computer user. Application programs make calls to, or use, the operating system to accomplish lower level tasks.

1. Operating Systems

The operating system is the inner-most software layer of a computer system according to the "virtual machine" model (Tanenbaum, 1990). It accomplishes tasks for users and/or the application programs and shields them from complex hardware details. Transparent to users and applications, the function of the operating system is to present the user with the equivalent of an extended machine or virtual machine that is easier to program than the underlying hardware. Its primary task is to keep track of resource usage, to grant resource requests and account for their usage, and to mediate conflicting requests from different programs and users (Tanenbaum, 1987).

At their advent, personal computers were initially equipped with 4 KB of main memory. The operating system had to be small enough to be loaded into this small memory space and still leave room for an application program to run. The early developers of personal computers and their operating systems did not expect these machines to grow in popularity as they have. The operating system was written to provide compactness and functionality in a "personal" environment. This meant one user, one program at a time. Under MS-DOS, anyone with basic knowledge can access and/or change any

file or memory location. The current trend is toward personal computer power houses shared by several workers able to run several applications simultaneously utilizing up to 8 MB of main memory. With multiple users instead of the envisioned personal use, MS-DOS does not provide any measure of security. In examining MS-DOS it is clear that it has limitations which cripple its capability to grow into a full-fledged operating system capable of supporting and managing systems which are now in demand.

MS-DOS's major limitation is that when conceived, it allotted only enough bits in its address format to access a maximum of 640 kilobytes of main memory directly. This limit remains in place today because of market pressures for downward compatibility. The most powerful applications programs tend to use most of the 640 kb of memory leaving only enough for the underlying operating system. To install security mechanisms in MS-DOS would undoubtedly reduce the memory space available for use by application programs to an even lower value. It seems that the market pressure for freeing up memory for applications is far greater than any pressure to add security functions to MS-DOS.

Although most operating systems for large systems provide adequate security functions, MS-DOS continues to serve as the personal computer standard with virtually no security capability. Market pressure for compatibility and

maximum application space will defeat any move to retrofit MS-DOS with security functionality.

2. Utilities

Utilities are separate system programs that accomplish tasks for users. Their normal function is system management. Since they are optional, commercial software programs are not written to use them. Utility programs are very important in security of personal computer systems. Because the operating system has no security capability, personal computer users often use utility programs to protect their data and programs. There are several different ways in which utility programs are commonly used for security in the personal computer environment. These include encryption of data, password hard disk drive locks with or without hardware locks, and disk residue eliminators. The best commercially available solutions include elements of all three (Stephenson, 1989).

Encryption of data using utility programs provides excellent security of data. The application program can be run by intruders but the data they receive will be nonsense unless first decrypted. Encryption and decryption can be accomplished automatically using batch command files. There are two limitations which come to mind in using data encryption utilities. Data file encryption and decryption are disk intensive activities and consequently are very

slow. Additionally, simply securing the data does not keep intruders from running the application program. It simply keeps the intruder from understanding the data. In some cases it may be desirable to ensure intruders are unable to run the application program at all.

Password hard disk drive boot locks are programs which require password authentication to boot and subsequently access the hard drive. They are fast, compact and work well against casual, novice intrusion attempts. Without hardware enhancements, however, they can be bypassed if the intruder boots the computer from a bootable MS-DOS floppy (Stephenson, 1989).

Additionally, access to even non-sensitive programs on the protected system requires password authentication. This limits the use of computer resources to trusted password holders only. In many cases it is desirable to secure only a portion of the functions the personal computer helps perform.

Other utilities rid secondary memory of residue. When files on personal computers are deleted their data remains. The operating system simply deletes the file from the directory, rendering it unlocatable. Intruders can read or copy portions of the memory media in search of sensitive data. Simply deleting files does not protect the information. Utilities such as Norton's *wipe disk* and *wipe*

file rewrite the disk or file entirely with meaningless data. This destroys all residue left from sensitive files.

These types of utilities are often bundled with hardware which disallows booting from any disk except the one protected by the software.

3. Applications

Application programs are the outer layer of software in the virtual machine model. The application software is a program which interfaces with the user and ensures that the tasks the user wishes to accomplish are completed. The application program makes calls to the operating system to accomplish low level tasks in order for the application to accomplish tasks initiated by the user. The application software is shielded from hardware details by the operating system.

The operating system, MS-DOS, provides no security capability and utilities leave possible back doors and require password access procedures for all applications. If application programs provide their own security capability only programs which require security would require passwords for access. Moreover, common back doors associated with security utility programs are closed to intruders when application programs contain protection schemes. Application programs that need no protection are not limited by running under a larger, hypothetical, security-capable

operating system which would use more of the 640 kb main memory than the unprotected MS-DOS. A minor drawback to applications providing their own protection is that the consequential increase in program size occurs in each secured application program. This is a minor drawback as the additional required disk storage space would small. The additional RAM would be required only by programs needing protection, thereby freeing maximum main memory for larger unprotected programs.

C. DATA

Two views of data security prevail: protection against inadvertent data loss and protection of unauthorized access to sensitive data. Inadvertent data loss is a problem of valuable, but not necessarily sensitive, data (Mensching and Adams, 1991). Procedures for precluding inadvertent data loss have been common knowledge since the personal computer's inception and will not be addressed here. Since the operating system as described previously provides no built-in file protection measures, data file encryption must be used to secure data in personal computers.

Utilities are commonly used to encrypt and decrypt data files to ensure protection of sensitive data. Some hardware add-on boards also possess the capability to automatically encrypt and decrypt data files. There are many different

algorithms to encrypt and decrypt data. Some of which are considered to be safer than others. The Data Encryption Standard (DES) is the most common one, initially developed for the U.S. government for use by the general public.

D. PERSONNEL

Sensitivity to security issues and an attitude of responsibility on the part of all users in a personal computer environment are necessary for other measures to succeed in providing security. Whereas mainframes and other large systems have separate locked rooms and expert operators shielding them, personal computers are vulnerably distributed throughout an organization. For instance, no security system can succeed if a user leaves the area while a sensitive application is running. No matter how strong the security system, it is useless unless personnel have a healthy attitude toward security and are sensitive to possible threats (Pfleeger, 1989).

III. THE RELAY RACE APPROACH

A. INTRODUCTION

In view of the personal computer operating system's inability to provide security and the limitations associated with security modules and utilities, it becomes worthwhile to explore new techniques for securing individual application programs. Three major threats to the security of an application can be countered, to include unauthorized execution of the main program, data disclosure and unauthorized execution of parts of the program by executing subprograms directly. Traditional methods cover encryption of data files and securing main programs, while the Relay Race Approach extends protection to the subprogram level.

1. Application Access Control

Personal computers are often used by different individuals running different application programs (Gogan, 1991). In most cases, all applications are stored on the same hard disk drive. Allowing access to certain programs by certain individuals while limiting access to valid users of other protected programs stored on the same disk is no trivial task in the PC environment. Since the MS-DOS operating system provides no security kernel, the solutions must be coded into the application programs. Each application program must check for access authorization and

take required measures to secure itself against intrusion. This is usually accomplished by an application-oriented Password checking scheme which protects the application at the main menu level.

2. Data File Security

Intrusion is usually for the purpose of achieving access to the system data. One intrusion technique is to bypass the application programs entirely and attempt to gain access to the system data files directly. An intruder could simply browse the file or copy it for later examination at another computer. To overcome this problem, data files must be encrypted.

3. Intra-application Controls

The growth in application software capabilities and the consequent growth in size has dictated that applications be designed as a collection of programs. In such a scheme, a main program calls on subprograms to accomplish specific tasks in support of the system. The main program can be secured with a password-checking scheme to prevent its unauthorized execution. However, access to functions and data can sometimes be achieved by executing subprograms directly without the main program, as depicted in Figure 3.1. To preclude this type of intrusion some method of ensuring that all subprograms are called by their proper calling programs or subprograms must be devised. The

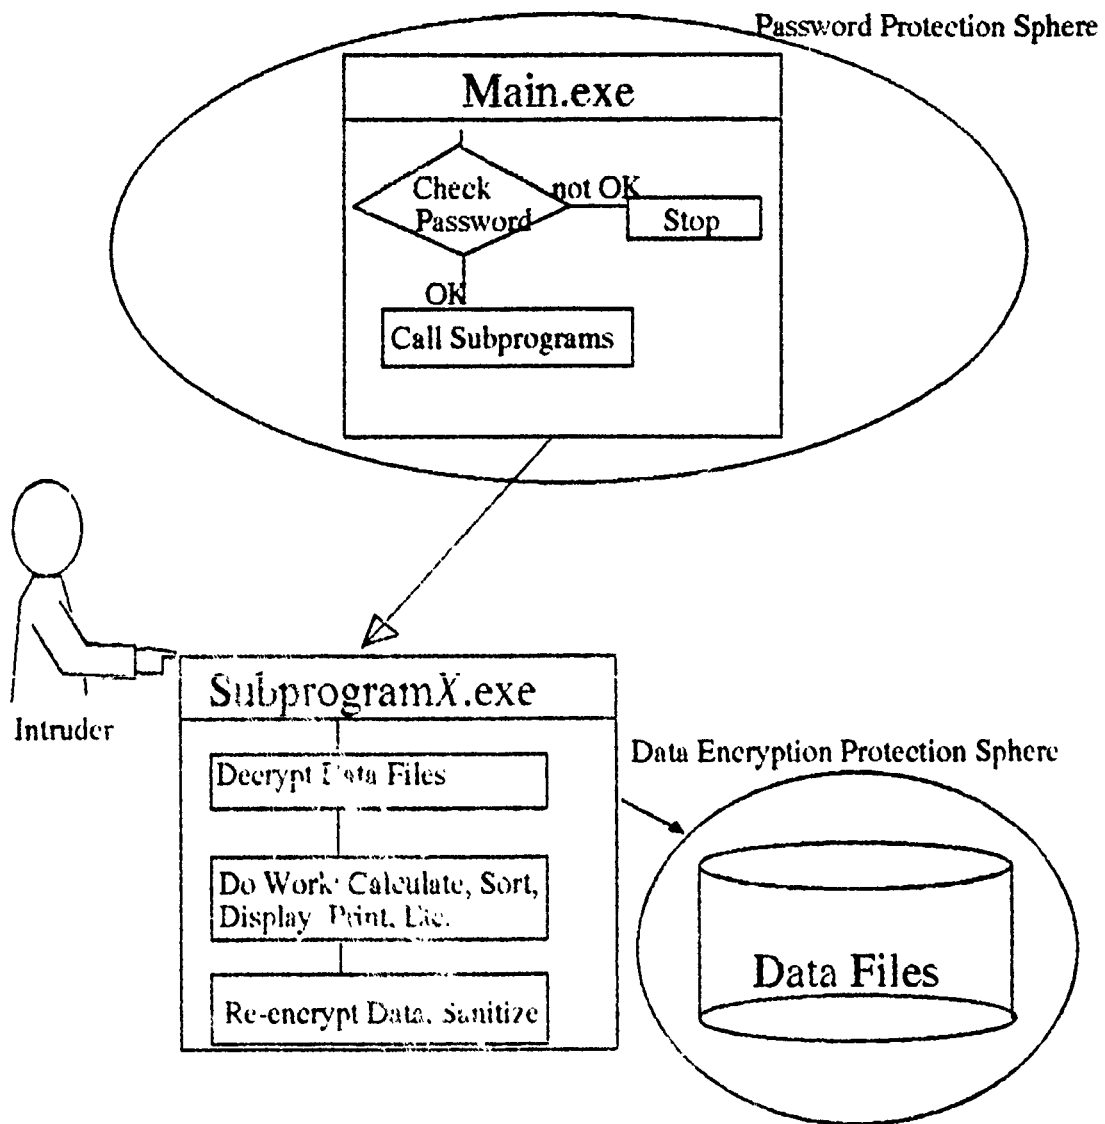

Figure 3.1: Password and Encryption Spheres of Protection

approach explored in this research will be called the relay race approach.

B. IMPLEMENTATION CONCEPTS

In order to counter the three threats three methods of protection are implemented in The Relay Race Approach. The first two measures are commonly used in the personal computer environment in an attempt to secure applications. One is basic password checking upon execution ensures user authorization, and the second employs automatic data encryption, decryption and deletion preclude theft of raw data files. However, to preclude program execution via an unprotected subprogram, all subprograms will check for a parameter which can only be valid if the subprogram was called via the main program as illustrated in Figure 3.2. This is a unique measure applied to individual application programs and it is from this third measure that the approach receives its name. In much the same way relay racers must pass a baton or be disqualified, subprograms must receive a certain parameter and pass it to subsequent subprograms or the program execution will be halted by the security system.

1. Password Storage and Management

There are two methods of storing valid passwords to be used by the system to authenticate users: including valid passwords in program source code and storing valid passwords

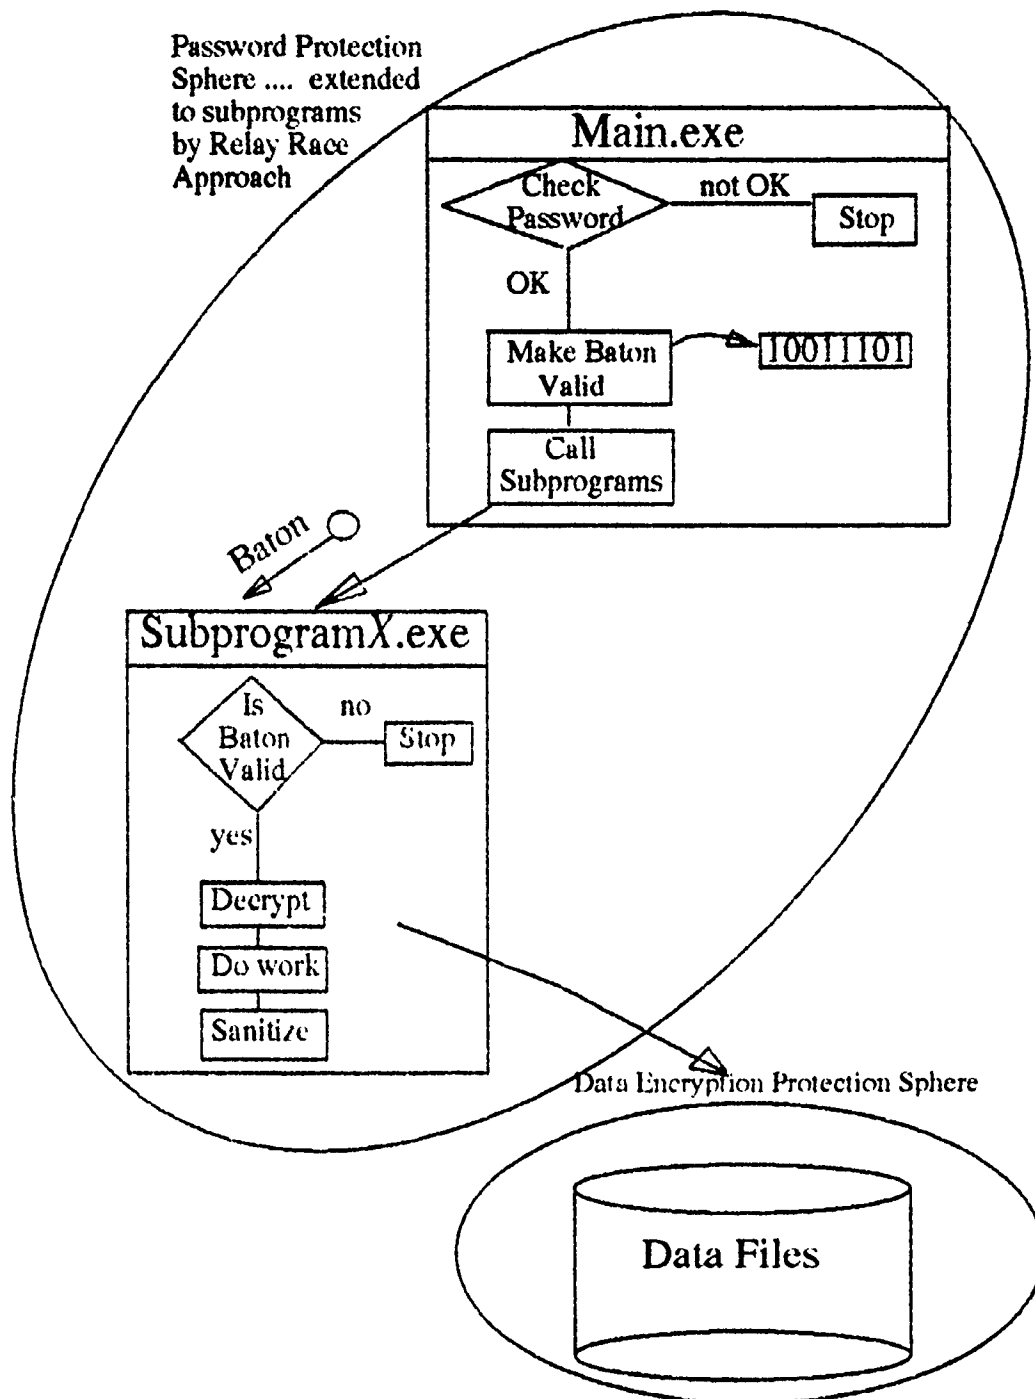

Figure 3.2: Password and Encryption Spheres of Protection extended to subprograms using the Relay Race Approach.

in encrypted data files. Including passwords in source code provides simplicity and security but requires recompilation for each password change. Using encrypted data files containing valid passwords precludes requirement for source code dissemination to user/ administrator but requires thoughtful implementation to ensure security. An intruder could encrypt his/her own password file with a different key and replace the real password file with his/her version (same filename). In order to defeat this intrusion scheme the system must check to determine whether the password file is real or one planted by an intruder. The valid password file will contain a password to be checked against one in the compiled code. The intruder's file would not work if it did not contain this file checking password. A combination of both encrypted data file and compiled password ensures security and precludes source code dissemination and recompilation for routine password changes.

2. Baton and Baton Passing

In order to ensure that subprograms are executed only when called by proper calling programs a global variable, or parameter, can be set upon password authentication and passed from the main program to the called subprograms. Subprograms can, in turn, pass the same parameter to any subprograms they call. Each subprogram can begin execution by checking this parameter before executing

further and halt processing if the parameter is invalid. This is analogous to a relay race at a track meet. Without the baton being properly passed and received the relay team cannot complete the race.

3. Data File Encryption

Two types of encrypted data files are required for the relay race baton scheme: password file and data storage files. The password file is decrypted, and the decrypted file is then read and deleted. The decryption process leaves the encrypted file intact so that when the system deletes the decrypted files, the original encrypted password file remains for use in future access attempts. Data storage files must be decrypted for reading and reencrypted if new data is added or other changes are made. Once again all files decrypted during a process need to have the decrypted copy deleted as soon as possible after they are re-encrypted.

IV. APPLICATION IN A THIRD GENERATION LANGUAGE ENVIRONMENT

A. ENVIRONMENT DESCRIPTION

A simple test application was developed in compiled MS-BASIC. BASIC was chosen as the third generation language for a prototype due to its relatively low power and programmers' wide exposure to it. If the relay race scheme can be implemented in BASIC, it is reasonable to assume that it is possible to implement it in any of the known third generation languages.

B. APPLICATION DESCRIPTION

The prototype application is a simple, menu-driven, maritime minefield planning program designed to minimize the necessity for accurate small scale plotting on geographic charts. The program has options to input planning data, calculate mine drop instructions, save instructions to disk, and print instructions. The application programs and data are protected using The Relay Race Approach.

The MS-DOS directory presentation for the application is provided in Figure 4.1. BASRUN20.EXE is a runtime package required for applications compiled separately such as the minefield planning application. MFPLAN.EXE is the main program containing password checking code and opening menu. The remaining .EXE files are subprograms which accomplish

the application's tasks. \$ED.MNQ and \$ED.NMQ are encrypted data and password files respectively.

\$ED	MNQ	560	5-19-91	9:24p
\$ED	NMQ	128	2-10-91	6:57p
BASRUN20	EXE	63046	6-25-85	4:42p
MFPLAN	EXE	3415	5-19-91	7:55p
MINECALC	EXE	4615	5-19-91	7:56p
MINEPRNT	EXE	2503	5-19-91	7:57p
MINESAVE	EXE	2887	5-19-91	7:56p
MLRETREV	EXE	2279	5-19-91	7:57p

Figure 4.1: MS-DOS Directory presentation of the application

The threat of intrusion via subprogram defeating the password authorization and data encryption without baton passing is illustrated in a structure chart of an intrusion attempt (Figure 4.2). When unprotected, an intruder needs only to write a small BASIC program to call MLRETREV.EXE and MINEPRNT.EXE in order to gain access to the system's sensitive data. By combining password checking, data encryption and the Relay Race Approach, this intrusion is thwarted (Figure 4.3).

C. TRANSFORMING CONCEPTS TO CODE

1. Handling Passwords and the Baton

The first operation the scheme must accomplish is password checking. This operation is be accomplished as early as possible in the application. Figure 4.4 contains

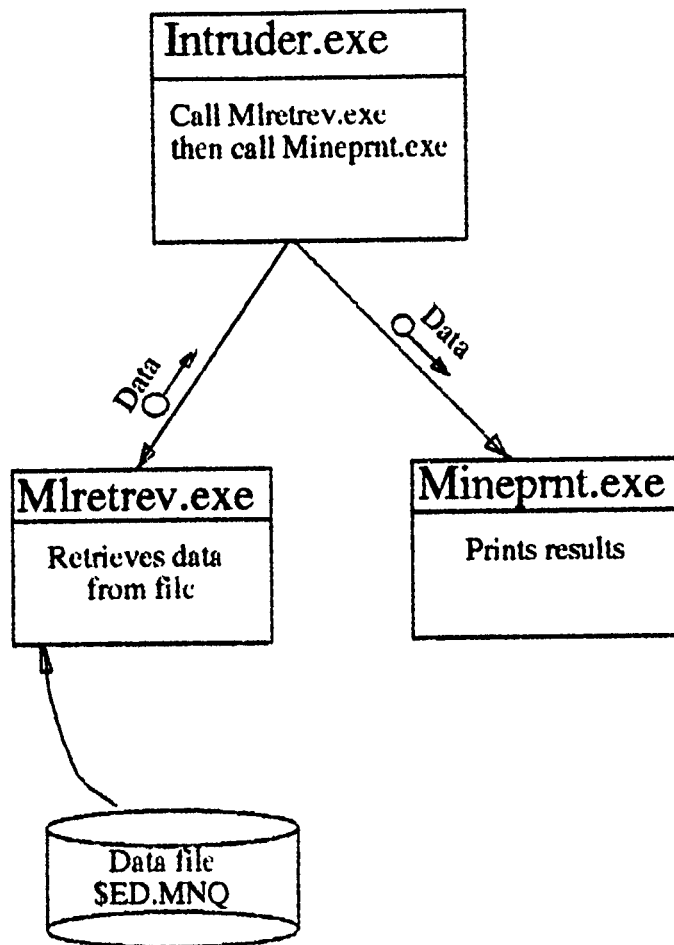

Figure 4.2: Structure chart illustrating how an intruder's program could call subprograms and achieve data access.

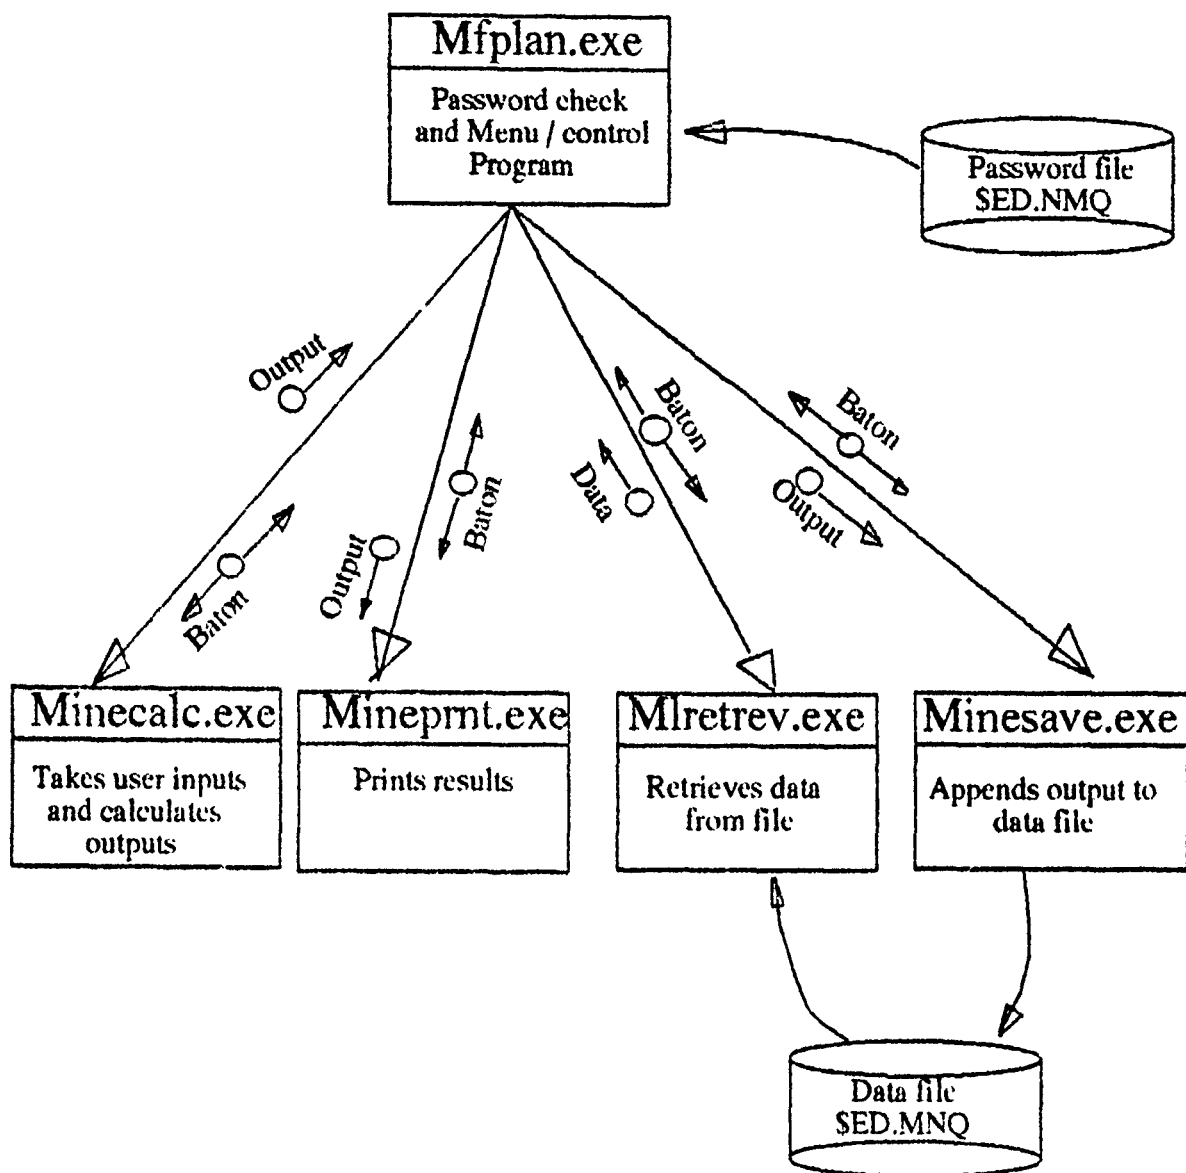

Figure 4.3: Structure chart of Mine - field Planning Program

the required BASIC source code to handle passwords and password checking and initialize the security baton. Line 9 allows the program to be recalled from subprograms without requesting a password each time the main menu appears. Lines 40, 50 and 60 blank the display screen for password entry, input password and return normal function to the display screen. Line 70 creates a decrypted copy of the valid password file and names it "PWORD.DAT". During the execution of the "RCRYPT" program, the user will be prompted to enter an encryption key twice. Line 80 opens the PWORD.DAT file for input. Lines 90, 100, 110 initialize several variables to be used: N, a loop counter; FOUND\$, a flag indicating whether a password is found to be valid or not; and BATON\$, the global variable or parameter passed to subprograms to verify that access authorization has been checked prior to subprogram execution. If the password file is found to be empty, line 120 will call the violation routine, (lines 220-290). Lines 140 and 150 input and check the first entry in the password file and ensure it is "scud". This defeats intruders who might plant their own encrypted password file in place of the original. If an imposter password file is detected the violation routine is run. Lines 160-200 are the password checking loop where the input password (PASSWORD\$) is checked against each valid password in the file (VALIDPWORD\$(N)). If end of file (EOF)

is reached without a match the violation routine is run. If a match is found, lines 300-320 are run in order to close the password file, delete it and set the security baton (BATON\$) valid. This allows subprograms to be called and run. The violation routine (lines 220-290) also closes and deletes the password file. Lines 240-260 provide a pause situation allowing displayed text message to be read by users before continuing program execution. Lines 350 to 450 represent location of functioning non-security related application code.

```

9 IF BATON$ = "VALID" then GOTO 330
10 LOCATE 13,10
20 PRINT "Enter your password and press ENTER."
30 LOCATE 15,15
40 COLOR 0

400   P R O G R A M
450   B O D Y )
500 END

```

Figure 4.4: Code required to check user's password and set "baton" variable

2. Called Subprogram Requirements

Subprograms require very little additional code to accomplish the relay race scheme. As the baton is passed by the COMMON mechanism (sharing variables and values among programs), a simple check of the security baton (BATON\$) must be made before each program execution. If the value passed by this variable is valid, execution continues. If the value passed by this variable is found to be invalid, it means that the subprogram was called without valid password authentication. A violation routine is run and the program is aborted. Required source code for subprograms is presented in Figure 4.5.

```
3 OPTION BASE 1
4 DIM YTD(10),TTD(10)
5 COMMON BATON$,NA$,LAH$,IPLAD,IPLAM,IPLAS,LOH$,
  IPLOD,IPLOM,IPLOS,SPD,TRK,N,YTD(),TTD()
20 IF BATON$ = "VALID" GOTO 30 ELSE GOTO 60
30 ( P R O G R A M
40   - - - - -
50   B O D Y )
60 LOCATE 17,10
70 PRINT "Security Violation!"
80 LOCATE 19,10
90 PRINT "Press any key to continue."
100 A$ = INKEY$
110 IF A$ = "" then 110
120 END
```

Figure 4.5: Code required in subprograms

3. Data Encryption, Decryption and Access Requirements

a. Data Encryption Utility

The encryption program used in this prototype is RCRYPT.COM, an MS-DOS utility. Many different data encryption utilities are available and most will work within this scheme. The application may need to be modified slightly depending on whether the encryption utility requires the key to be entered on the command line as a parameter or prompts the user for the key during execution. The RCRYPT.COM utility in the prototype prompts for the key during execution.

b. Data File Manipulation

This prototype uses one password file and one data file. A flat file of records is used because data for this application is small and response time is not a critical issue. As shown in Figure 4.6 most of the data manipulations focus on decrypting and reading data. One subprogram (MINESAVE) allows for appending data to the data file. This case requires decrypting the data file, appending new data to the file and re-encrypting the file. The source code required for this operation is presented in Figure 4.7.

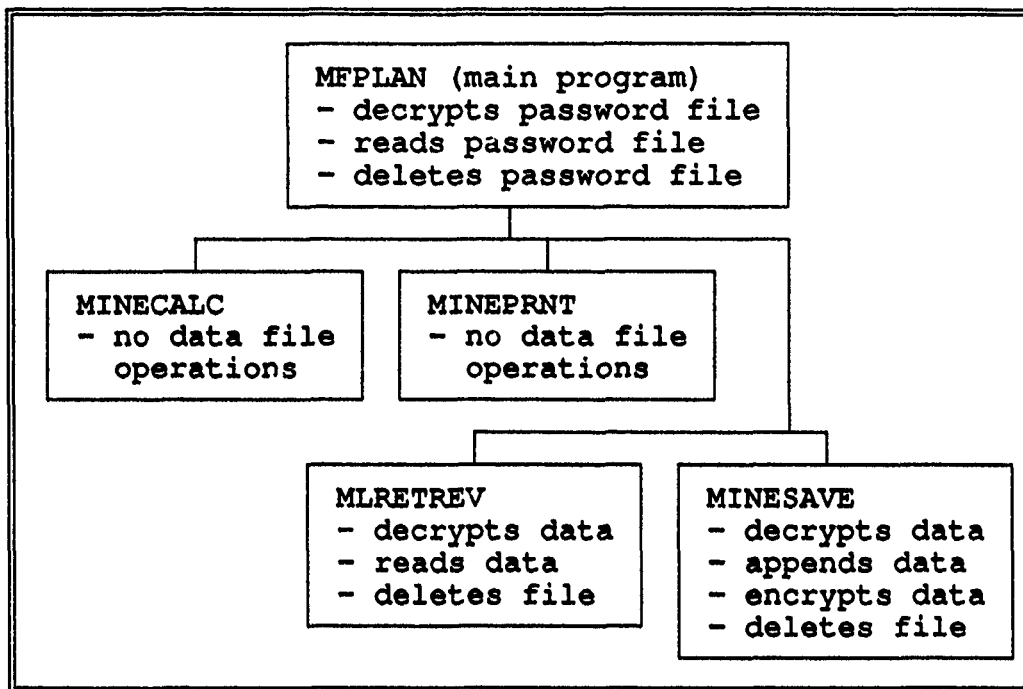

Figure 4.6: Description of data file manipulations for each of the programs in the Basic prototype application.

```

40 PRINT "What name would you like to call the data?"
50 INPUT NA$
60 SHELL "RCRYPT $ED.MNQ MINE.DAT"
70 OPEN "MINE.DAT" for APPEND as #2
80 WRITE #2,NA$,LAH$,IPLAD,IPLAM,IPLAS,LOH$,IPLD,
    IPLM,IPLOS,SPD,TRK,N
90 FOR B = 1 to N
100 WRITE #2,YTD(B),TTD(B)
110 NEXT B
120 CLOSE #2
130 SHELL "RCRYPT MINE.DAT $ED.MNQ"
140 KILL "MINE.DAT"
  
```

Figure 4.7: Code required for data file manipulation in MINESAVE subprogram

c. System Administration

The application requires a system administrator to accomplish certain tasks. These tasks include steps to start the system, accomplishing data file housekeeping and changing passwords. Since it is not desirable to supply source code to all users, the application deliverables should include information indicating what the first entry in the password file needs to be. This entry should be unique or nearly unique among different copies of the application to preclude one systems administrator from intruding into another's copy. For example, line 150 Figure 4.4 character string "scud" (FILECHK\$) should be identified as the required first entry in the password file and should be different for each copy of the application. To start the system the administrator should add his/her desired passwords, nine at most, to the required first entry, encrypt the file with the desired case sensitive key and the name "\$ED.NMQ" and delete the un-encrypted copy of the password file.

The application should also include a data file with one set of test data included to preclude the system from attempting to decrypt and append to an empty file. A copy of this original data file should be maintained by the administrator and used for data housekeeping operations. The data file, like the password file, needs to be encrypted

and named in accordance with lines 130 and 70 of Figures 4.7 and 4.4 respectively.

Changing the passwords should be done regularly in any system and should be easy to accomplish so as not to discourage changes when needed. To change passwords, run RCRYPT.COM directly on the \$ED.NMQ file and edit the file with new passwords. The required first entry of the file should not be changed or the system will reject the new password file as bogus. Re-encryption of the password file using a new encryption key is needed. Changing the key each time passwords are changed maximizes security.

V. APPLICATION IN A FOURTH GENERATION LANGUAGE ENVIRONMENT

A. ENVIRONMENT DESCRIPTION

The Relay Race Approach was installed into a previously implemented DBaseIV database application. DBase was chosen because of its widespread familiarity and its non-procedural nature. If the approach could be easily grafted into an existing DBase IV generated application, it would be an effective approach for securing other existing applications.

Fourth generation languages are often used in environments where end users build applications. Security may not be considered when users create applications. The Relay Race Approach shows promise as an efficient security measure for these existing end user applications.

The DbaseIV application generator allows users or developers to create fully functional menu driven database applications with little or no coding. Database structures, forms, reports and queries are created using user friendly graphical interfaces and then are combined to work together by the application generator. The application generator generates source code with comments which is compiled into object code that can be run either in the DBase IV environment or with a run-time module.

B. APPLICATION DESCRIPTION

The application is the user version of an automated dive log. It is used for users to enter SCUBA diving events, and query reports such as logs or qualification reports from the database. There is another version which accesses the same database which is used by the system administrator for marketing and other business and organizational functions.

The application accesses four database files: DIVER.DBF, SITE.DBF, DIVE.DBF and QUAL.DBF. It uses one data entry form file, DIVEFORM.SCR. Two query (.QBE) files were slightly modified for use: JOIN1.PRG and QUALLIST.PRG. Two report files were built and used: LOG_REPO.FRM and QUALRPT.FRM. Finally, the application generator created two program files: DLUSER.PRG and USERBAR.PRG.

Since the Relay Race Approach depends on passing parameters between programs, the structure of the application must be understood before the approach can be installed into an existing application. Since the source code was 95 percent generated by DbaseIV the application must be reverse engineered, yielding a structure chart needed for understanding. Figure 5.1 is the structure chart for the application. Only JOIN1.PRG and QUALLIST.PRG can access the data, so only procedures which can possibly call them need to have the additional source code installed.

Figure 5.1: Structure Chart of Dive Log Application

These are DLUSER and MPDEF in DLUSER.PRG file, ACT03, ACT04 in USERBAR.PRG file, and JOIN1.PRG and QUALLIST.PRG files.

C. TRANSFORMING CONCEPTS TO CODE

1. Handling Passwords and the Baton

Checking password validity is accomplished first and the code required for this was inserted into the main program, DLUSER.PRG. Figure 5.2 shows the additional source code inserted at the very beginning of the DLUSER.PRG file. The set color commands ensure that the password is not echoed to the screen when the user types their's. In order to get the prompt "Enter Password" on the screen and not the password itself, the prompt and the acceptance of the value for variable "PWORD" had to be separated by the set color command. This is why the ACCEPT string is a space. Set color is used again to return the screen to normal. Since most Dbase IV users will have the capability to compile programs, the passwords were compiled rather than stored in an encrypted file. The logic in the IF / ELSE clause is such that if no password is entered, and the error message which occurs is "ignored" by the user, the program VIOLATIO.PRG will be run, not the rest of DLUSER.PRG. Dbase defaults to the first statement when an error is encountered in an IF/ELSE clause and the user selects "IGNORE" at the error prompt. VIOLATIO.PRG displays a violation message and

terminates the program. If the password is found to be valid the data files are decrypted. Since the baton in DBase can be a true parameter instead of a shared variable as was the case in BASIC, a variable does not need to be set. When a procedure is called it simply needs to be called with a value which will be checked by the called procedure. Figure 5.3 illustrates the correct syntax for calling programs and procedures with the parameter required.

```
@3,3 SAY "Enter Password: "  
SET COLOR OF NORMAL TO B/B  
ACCEPT " " TO PWORD  
SET COLOR OF NORMAL TO W+/B  
IF (.NOT. PWORD="TIGRIS").AND.(.NOT. PWORD="SCUD")  
    .AND.(.NOT.PWORD="BAGDAD")  
    DO VIOLATIO  
ELSE  
    RUN PKUNZIP ADLDATA -sIRAQ  
    ** Rest of Program **
```

Figure 5.2: Code required for password checking in the main program for the Dive Log application.

```
** Calling Program or Procedure **  
DO MPDEF WITH "GOOD"  
  
** Called Program or Procedure **  
PARAMETER BATON  
ON ERROR CANCEL  
IF .NOT. BATON = "GOOD"  
    DO VIOLATIO  
ELSE  
    ** Rest of Program **
```

Figure 5.3: Code required for calling subprograms and procedures with parameters.

2. Called Procedures or Subprograms Requirements

Called subprograms or procedures which receive the security parameter BATON must contain the PARAMETERS statement as shown in Figure 5.3. It was discovered during testing that if an intruder attempted to call a subprogram or procedure directly without the required parameter, Dbase displays an error message displaying the (IF .NOT. BATON = "GOOD") line of source code and a prompt "PARAMETER NOT FOUND". This would give the intruder information required to successfully call the subprogram or procedure on his next attempt. The "ON ERROR CANCEL" line terminates program execution when any error occurs to remedy the situation. The IF/ELSE clause checks for the security baton and runs the violation procedure or the rest of the program accordingly.

3. Data Encryption, Decryption and Administration.

Since the application uses four different data files the PKZIP/PKUNZIP utility programs were selected for encryption and decryption of data files. It allows for compression and encryption of multiple files into one single file. As depicted in Figure 5.2 the encryption key "IRAQ" is compiled into the program instead of being prompted from and entered by the user.

The procedure ACT05 in the USERBAR.PRG file, (Figure 5.1), is executed to exit the system. Data encryption and

residue housekeeping is accomplished here. The required code is shown in Figure 5.4

```
RUN PKZIP ADLDATA -m -SIRAQ *.DBF
```

Figure 5.4: Code required for encrypting data files and removing the decrypted data files.

The system administrator has only to periodically recompile the source code changing passwords and encryption keys. Access to the source code should be limited to trusted personnel only as it contains information which would greatly simplify intrusion.

VI. THE RELAY RACE APPROACH AND LOCAL AREA NETWORK SECURITY

The explosion of personal computers in the workplace has led to the need for data communication and asset sharing among an organization's PCs. Local area networks (LANs) efficiently provide these attributes and are being utilized extensively today.

A. ELEMENTS AND FUNCTIONALITY OF LANS

LAN implementation includes installing LAN hardware expansion cards in the computers which are to be linked, linking the computers together using a cabling system, and installing a LAN operating system on the machines. One of the machines is designated as the server and the rest are clients. The full operating system resides on the server while only a shell or subset resides on each client. In popular PC LANs the network operating system still utilizes MS-DOS but provides added network functions.

Communication between machines or nodes in a network involves multiple communication protocols. Each protocol level uses functions provided at lower levels by lower level protocols.

B. SECURITY IN LANS

Most LAN operating systems provide security functions capable of multi-level security of files and physical

devices. These measures combined with certain physical security measures involving the network server can protect assets against casual intrusion attempts. However, if physical access to the network server can be gained an intruder could attempt to load a different copy of the network operating system onto the server and give himself access to protected files and/or devices. Many LANs place printers and other peripherals along side the server and the server therefore cannot be physically isolated from the users or public.

C. ENHANCING OVERALL LAN SECURITY

Even though network operating systems often provide security features, the Relay Race Approach can significantly strengthen overall security. The Relay Race Approach provides efficient security at the application layer complementing security features implemented at the LAN operating system layer. For example, if an intruder were capable of accessing the LAN server, load a different copy of the LAN operating system and attempt to access a protected application, additional security provided by the Relay Race Approach would significantly hamper his attempts. The additional layer of security would most likely end the intruder's attempt: at least for that session. Additionally, combining security measures implemented at the

LAN operating system layer with those at the application layer can reduce requirements for "armor plated" physical security measures such as heavy duty locks, doors or cabinets for the network server.

Both prototype applications were installed on a LAN. Both executed as expected and illustrated feasibility of the Relay Race Approach as a security measure for applications running on LANs.

VII. CONCLUSIONS

Personal computer security is an issue of increasing importance to computer professionals. It is valuable to explore efficient methods of providing or enhancing PC security. The Relay Race Approach provides or enhances security in the PC environment efficiently. The Approach can be strengthened using deceptive measures to thwart intrusions by all but those thoroughly familiar with the application source code.

A. THE NEED

The increased need for PC security is evident in view of several recent trends. First, PCs are being used in an increasing number of different business areas. These include those areas where sensitive processing is common. Secondly, more persons are becoming familiar enough with PC's and MS-DOS to be considered capable of casual intrusion into marginally protected PC environments. Finally, the increase in public sensitivity to privacy of information issues dictates the need for increased security in areas once thought to be of a non-sensitive nature.

B. REQUIRED ATTRIBUTES

For these reasons an approach with the following attributes would be of significant value. It should be

compact, as application program size is of great concern in the PC environment. The approach should be flexible or multi-leveled, that is, it should allow public access to some applications and limit access to other application(s) to only their specified set of authorized users. The approach should be easy to implement, even in existing applications. Increasing end-user application development makes this a valuable attribute. The Relay Race Approach exhibits these desired attributes and is strong enough to withstand casual attacks from intruders with strong knowledge of MS-DOS and PCs.

C. POSSIBLE ENHANCEMENTS

The relay approach depends on the premise that an intruder does not have access to the application source code and knowledge of how the approach was implemented in the application. There are two modifications which could enhance security just in case knowledge of the approach and/or application source code is compromised: unique application copies and deceptive and dynamic baton variables. Additionally, disk file residue eliminators could strengthen security.

1. Unique Application Copies

First, it would be important to make different copies of the application utilize unique or nearly unique

password files. This would be accomplished by compiling many versions of the program, each using a different first entry in the password file (the password file check variable). This would defeat an intruder who might have one copy of the application and attempt to insert his password file into another system and using it to gain access to the other system's data.

2. Deceptive and Dynamic Batons

To further help deceive intruders who might gain access to the program source code, the "baton" may be concealed. Suppose in the Basic application the baton variable were "MINEDIST#" instead of "BATON" and was of type integer, Figure 4.4. This would slow a potential intruder's conceptualization as he browses the source code in search of security hints. Additionally, dynamic batons can be employed. Such a baton variable can be set to valid indirectly through one or more intermediate variables which might appear to be accomplishing some arithmetic operations. The value given to the baton variable may also change often but retain some characteristic for the validity check. For instance, the baton could change value but retain even divisibility by 17 and the validity check would be designed to test for that.

3. Disk File Residue Eliminators

Finally, using a filewipe type residue eliminating program instead of simple MS-DOS delete command in the application would provide an extra degree of security to counter random disk sector searches.

The Relay Race Approach provides efficient, casual security for personal computer applications in today's environment of increasing PC security Threats.
